

2e,

For $k=3$ and $k=7$, Both are having the good performance, we can't decide which one is the best.

$k=3$ is good if we don't consider the age metric in the data set but when we include age metric then $k=9$ gives the best performance.

Just by comparing, we cannot decide the better performance.

To decide only one nearest neighbor, we need more trained data set.
